SARS-CoV-2 is the etiological agent responsible for the global COVID-19 outbreak. The main protease (M^{pro}) of SARS-CoV-2 is a key enzyme that plays a pivotal role in mediating viral replication and transcription. We designed and synthesized two lead compounds (11a and 11b) targeting M^{pro}. Both exhibited excellent inhibitory activity and potent anti-SARS-CoV-2 infection activity. The X-ray crystal structures of SARS-CoV-2 M^{pro} in complex with 11a or 11b, both determined at 1.5 Å resolution, showed that the aldehyde groups of 11a and 11b are covalently bound to Cys145 of M^{pro}. Both compounds showed good PK properties in vivo, and 11a also exhibited low toxicity, suggesting that these compounds are promising drug candidates.

In late December 2019, a cluster of pneumonia cases caused by a novel coronavirus (CoV) was reported in Wuhan, China (1–3). Genomic sequencing showed that this pathogenic coronavirus is 96.2% identical to a bat coronavirus and shares 79.5% sequence identity to SARS-CoV (4–6). This novel coronavirus was named severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) by the International Committee on Taxonomy of Viruses, and the pneumonia was designated as COVID-19 by the World Health Organization (WHO) on February 11, 2020 (7). The epidemic spread rapidly to more than 212 countries and was announced as a global health emergency by WHO (8). No clinically effective vaccines or specific antiviral drugs are currently available for the prevention and treatment of COVID-19 infections. The combination of α -interferon and the anti-HIV drugs Lopinavir/Ritonavir (Kaletra®) has been used, but the curative effect remains very limited and there can be toxic side effects (9). Remdesivir, a broad-spectrum antiviral drug developed by Gilead Sciences, Inc., is also being explored for

the treatment of COVID-19, but more data are needed to prove its efficacy (10–12). Specific anti-SARS-CoV-2 drugs with efficiency and safety are urgently needed.

A maximum likelihood tree based on the genomic sequence showed that the virus falls within the subgenus *Sarbecovirus* of the genus *Betacoronavirus* (6). Coronaviruses are enveloped, positive-sense, single-stranded RNA viruses. The genomic RNA of CoVs is approximately 30 k nt in length with a 5' cap structure and 3' poly-A tail, and contains at least 6 open reading frames (ORFs) (13, 14). The first ORF (ORF 1a/b), about two-third of genome length, directly translates two polyproteins: pp1a and pp1ab, because there is an a-1 frameshift between ORF1a and ORF1b. These polyproteins are processed by a main protease (M^{pro}), also known as the 3C-like protease (3CL^{pro}), and one or two papain-like proteases (PLPs), into 16 non-structural proteins (nsps). These nsps engage in the production of subgenomic RNAs that encode four main structural proteins (envelope (E), membrane (M), spike (S), and nucleocapsid (N) pro-

teins) and other accessory proteins (15, 16). Therefore, these proteases, especially M^{pro}, play a vital role in the life cycle of coronavirus.

M^{pro} is a three-domain (domains I to III) cysteine protease involved in most maturation cleavage events within the precursor polyprotein (17–19). Active M^{pro} is a homodimer containing two protomers. The CoV M^{pro} features a non-canonical Cys-His dyad located in the cleft between domains I and II (17–19). M^{pro} is conserved among CoVs and several common features are shared among the substrates of M^{pro} in different CoVs. The amino acids in substrates from the N terminus to C terminus are numbered as follows (-P4-P3-P2-P1, P1'-P2'-P3'-), and the cleavage site is between the P1 and P1'. In particular, a Gln residue is almost always required in the P1 position of the substrates. There is no human homolog of M^{pro} which makes it an ideal antiviral target (20–22).

The active sites of M^{pro} are highly conserved among all CoV's M^{pro}s and are usually composed of four sites (S1', S1, S2 and S4) (22). By analyzing the substrate-binding pocket of SARS-CoV M^{pro} (PDB ID: 2H2Z), novel inhibitors targeting the SARS-CoV-2 M^{pro} were designed and synthesized (Fig. 1). The thiol of a cysteine residue in the S1' sites anchors inhibitors by a covalent linkage that is important for the inhibitors to maintain antiviral activity. In our design of new inhibitors, an aldehyde was selected as a new warhead in P1 in order to form a covalent bond with cysteine. The reported SARS-CoV M^{pro} inhibitors often have an (*S*)- γ -lactam ring that occupies the S1 site of M^{pro}, and this ring was expected to be a good choice in P1 (23). Furthermore, the S2 site of coronavirus M^{pro} is usually large enough to accommodate the bigger P2 fragment. To test the importance of different ring systems, a cyclohexyl or 3-fluorophenyl were introduced in P2, with the fluorine expected to enhance activity. An indole group was introduced into P3 in order to form new hydrogen bonds with S4 and improve drug-like properties.

The synthetic route and chemical structures of the compounds (**11a** and **11b**) are shown in scheme S1. The starting material (*N*-Boc-*L*-glutamic acid dimethyl ester **1**) was obtained from commercial suppliers and used without further purification to synthesize the key intermediate **3** according to the literature (24). The intermediates **6a** and **6b** were synthesized from **4** and acids **5a**, **5b**. Removal of the *t*-butoxycarbonyl group from **6a** and **6b** yielded **7a** and **7b**. Coupling **7a** and **7b** with the acid **8** yielded the esters **9a** and **9b**. The peptidomimetic aldehydes **11a** and **11b** were approached through a two-step route in which the ester derivatives **9** were first reduced with NaBH₄ to generate the primary alcohols **10a** and **10b**, which were subsequently oxidized into aldehydes **11a** and **11b** with Dess-Martin Periodinane (DMP).

Recombinant SARS-CoV-2 M^{pro} was expressed and purified from *Escherichia coli* (*E. coli*) (18, 25). A fluorescently labeled substrate, MCA-AVLQ↓SGFR-Lys (Dnp)-Lys-NH₂, derived from the *N*-terminal auto-cleavage sequence from the viral protease was designed and synthesized for the enzymatic assay.

Both **11a** and **11b** exhibited high SARS-CoV-2 M^{pro} inhibition activity, which reached 100% for **11a** and 96% for **11b** at 1 μ M, respectively. We used a fluorescence resonance energy transfer (FRET)-based cleavage assay to determine the IC₅₀ values. The results revealed excellent inhibitory potency with IC₅₀ values of 0.053 $\pm$ 0.005 μ M and 0.040 $\pm$ 0.002 μ M, for **11a** and **11b** respectively (Fig. 2).

In order to elucidate the mechanism of inhibition of SARS-CoV-2 M^{pro} by **11a**, we determined the high-resolution crystal structure of this complex at 1.5-Å resolution (table S1). The crystal of M^{pro}-**11a** belong to the space group *C2* and an asymmetric unit contains only one molecule (table S1). Two molecules (designated protomer A and protomer B) associate into a homodimer around a crystallographic 2-fold symmetry axis (fig. S2). The structure of each protomer contains three domains with the substrate-binding site located in the cleft between domain I and II. At the active site of SARS-CoV-2 M^{pro}, Cys145 and His41 (Cys-His) form a catalytic dyad (fig. S2).

The electron density map clearly showed compound **11a** in the substrate binding pocket of SARS-CoV-2 M^{pro} in an extended conformation (Fig. 3A and fig. S3, A and B). Details of the interaction are shown in Fig. 3, B and C. The electron density shows that the C of the aldehyde group of **11a** and the catalytic site Cys145 of SARS-CoV-2 M^{pro} form a standard 1.8-Å C-S covalent bond. The oxygen atom of the aldehyde group also plays a crucial role in stabilizing the conformations of the inhibitor by forming a 2.9-Å hydrogen bond with the backbone of residues Cys145 in the S1' site. The (*S*)- γ -lactam ring of **11a** at P1 fits well into the S1 site. The oxygen of the (*S*)- γ -lactam group forms a 2.7-Å hydrogen bond with the side chain of His163. The main chain of Phe140 and side chain of Glu166 also participate in stabilizing the (*S*)- γ -lactam ring by forming 3.2-Å and 3.0-Å hydrogen bonds with its NH group, respectively. In addition, the amide bonds on the chain of **11a** are hydrogen-bonded with the main chains of His164 (3.2 Å) and Glu166 (2.8 Å), respectively. The cyclohexyl moiety of **11a** at P2 deeply inserts into the S2 site, stacking with the imidazole ring of His41. The cyclohexyl group is also surrounded by the side chains of Met49, Tyr54, Met165, Asp187 and Arg188, producing extensive hydrophobic interactions. The indole group of **11a** at P3 is exposed to solvent (S4 site) and is stabilized by Glu166 through a 2.6-Å hydrogen bond. The side chains of residues Pro168 and Gln189 interact with the indole group of **11a** through hydrophobic interactions. Interestingly, multiple

water molecules (named W1-W6) play an important role in binding **11a**. W1 interacts with the amide bonds of **11a** through a 2.9-Å hydrogen bond, whereas W2-6 form a number of hydrogen bonds with the aldehyde group of **11a** and the residues of Asn142, Gly143, Thr26, Thr25, His41 and Cys44, which contributes to stabilizing **11a** in the binding pocket.

The crystal structure of SARS-CoV-2 M^{pro} in complex with **11b** is very similar to that of the **11a** complex and shows a similar inhibitor binding mode (Fig. 3D and figs. S3, C and D, and S4A). The difference in binding mode is most probably due to the 3-fluorophenyl group of **11b** at P2. Compared with the cyclohexyl group in **11a**, the 3-fluorophenyl group undergoes a significant downward rotation (Fig. 3D). The side chains of residues His41, Met49, Met165, Val186, Asp187 and Arg188 interact with this aryl group through hydrophobic interactions and the side chain of Gln189 stabilizes the 3-fluorophenyl group with an additional 3.0-Å hydrogen bond (Fig. 3, E and F). In short, these two crystal structures reveal a similar inhibitory mechanism in which both compounds occupy the substrate-binding pocket and block the enzyme activity of SARS-CoV-2 M^{pro}.

Compared with those of **N1**, **N3** and **N9** in SARS-CoV M^{pro} complex structures reported previously, the binding modes of **11a** and **11b** in SARS-CoV-2 M^{pro} complex structures are similar and the differences among these overall structures are small (Fig. 4 and fig. S4, B to F) (22). The differences mainly lie in the interactions at S1', S2 and S4 sub-sites, possibly due to various sizes of functional groups at corresponding P1', P2 and P4 sites in the inhibitors (Fig. 4, A and C).

To further substantiate the enzyme inhibition results, we evaluated the ability of these compounds to inhibit SARS-CoV-2 in vitro (Fig. 5 and fig. S5). As shown in Fig. 5, compounds **11a** and **11b** exhibited good anti-SARS-CoV-2-infection activity in cell culture with EC₅₀ values of 0.53 ± 0.01 µM and 0.72 ± 0.09 µM using plaque-reduction assay, respectively. Neither compound caused significant cytotoxicity, with half cytotoxic concentration (CC₅₀) values of >100 µM, yielding selectivity indices (SI) for **11a** and **11b** of >189 and >139, respectively. Both immunofluorescence and quantitative real-time PCR were also employed to monitor the antiviral activity of **11a** and **11b**. The results show **11a** and **11b** exhibit a good antiviral effect on SARS-CoV-2 (Fig. 5 and fig. S5).

To explore the further druggability of the compounds **11a** and **11b**, both of the compounds were evaluated for their pharmacokinetic (PK) properties. As shown in table S2, compound **11a** given intraperitoneally (5 mg/kg) and intravenously (5 mg/kg) displayed a half-life (T_{1/2}) of 4.27 hours and 4.41 hours, respectively, and a high maximal concentration (C_{max} = 2394 ng/mL) and a good bioavailability of

87.8% were observed when the compound **11a** was given intraperitoneally. Metabolic stability of **11a** in mice was also good (Clearance (CL) = 17.4 mL/min/mg). When administered intraperitoneally (20 mg/kg), subcutaneously (5 mg/kg) and intravenously (5 mg/kg), compound **11b** also showed good PK properties (the bioavailability of intraperitoneally and subcutaneously are more than 80%, and a longer T_{1/2} of 5.21 hours when **11b** was given intraperitoneally). Considering the danger of COVID-19, we selected the intravenous drip administration to further study for the reason that value of the area under the curve (AUC) is high and the effect is rapid. Compared with **11a** administrated intravenously, the T_{1/2} (1.65h) of **11b** is shorter and the clearance rate is faster (CL = 20.6 mL/min/mg). Compound **11a** was selected for further investigation with intravenous drip dosing in Sprague-Dawley (SD) rats and Beagle dogs. The results showed (table S3) that **11a** exhibited long T_{1/2} (SD rat, 7.6 hours and Beagle dog, 5.5h), low clearance rate (rat, 4.01 mL/min/kg and dog, 5.8 mL/min/kg) and high AUC value (rat, 41500 hours*ng/mL and dog, 14900 hours*ng/mL). Those above PK results indicate that compound **11a** is worth to warrant further study.

An in vivo toxicity study (table S4) of **11a** has been carried out on SD rats and Beagle dogs. The acute toxicity of **11a** was measured on SD rats. No SD rats died after receiving 40 mg/kg by intravenous drip administration. When the dosage was raised to 60 mg/kg, one of four SD rats died. The dose range toxicity study of **11a** was conducted for seven days at dosing levels of 2, 6, and 18 mg/kg on SD rats and at 10-40 mg/kg on Beagle dogs. All animals received once daily dosing (QD), by intravenous drip, and all animals were clinically observed at least once a day. No obvious toxicity was observed in either group. These above data indicated that **11a** is good candidate for further clinical studies.

ACKNOWLEDGMENTS

We thank Prof. James Halpert and LetPub (www.letpub.com) for linguistic assistance during the preparation of this manuscript. We also thank the staff from beamlines BL17U1, BL18U1 and BL19U1 at Shanghai Synchrotron Radiation Facility (SSRF) for assistance during data collection. **Funding:** We are grateful to the National Natural Science Foundation of China (Nos. 21632008, 21672231, 21877118, 31970165, 91953000 and 81620108027), the Strategic Priority Research Program of the Chinese Academy of Sciences (XDA12040107 and XDA12040201) and Chinese Academy of Engineering and Ma Yun Foundation (No. 2020-CMKYGG-05) and Science and Technology Commission of Shanghai Municipality (Nos. 20431900100), and National Key R&D Program of China (Nos. 2017YFC0840300 and 2020YFA0707500 to Z.R.), and Science and Technology Commission of Shanghai Municipality (No. 20431900200), and Department of Science and Technology of Guangxi Zhuang Autonomous Region (No. 2020AB40007), and Frontier Biotechnologies Inc. for financial support. **Author contributions:** H. Y. and H. L. conceived the project. Y. X., L. Z., H. Y., and H. L. designed the experiments; W. D. and J. L. designed and synthesized the compounds; X. J. and H. S. tested the inhibitory activities; X. X., J. P., C. L., S. H., J. W., performed the chemical experiments and collected the data. B. Z., Y. Z., Z. J., F. L., F. B., H. W., X. C., X. L., and X. Y. collected the diffraction data and solved the crystal structure; Y. L. and X. C. performed the toxicity experiments. G. X., H. J., Z. R., L. Z., Y. X., H. Y. and H. L., analyzed and discussed the data. L. Z., Y. X., H. Y., and H. L., wrote the manuscript. **Competing interests:** The Shanghai Institute of Materia Medica has applied for PCT and Chinese patents which cover **11a**, **11b** and related peptidomimetic aldehyde compounds. **Data and materials availability:** All data are available in the main text or the supplementary materials. The PDB accession No. for the coordinates of SARS-CoV-2 M^{pro} in complex with 11a is 6LZE, and the PDB accession No. for the coordinates of SARS-CoV-2 M^{pro} in complex with 11b is 6MOK. The plasmid encoding the SARS-CoV-2 M^{pro} will be freely available. Compounds **11a** and **11b** are available from H. L. under a material transfer agreement with Shanghai Institute of Materia Medica. There is currently an international effort to join forces to design better inhibitors of SARS-CoV-2 M^{pro} as described in the following website: <https://covid.postera.ai/covid>. Surface representation of substrate-binding pocket of SARS-CoV M^{pro}

Fig. 1. Design strategy of novel SARS-CoV-2 main protease inhibitors and the chemical structures of 11a and 11b.

Fig. 2. Inhibitory activity profiles of compounds 11a (A) and 11b (B) against SARS-CoV-2 M^{pro} .

Fig. 3. M^{pro} -inhibitor binding modes for 11a and 11b. (A) Cartoon representation of the crystal structure of SARS-CoV-2 M^{pro} in complex with **11a**. The compound **11a** is shown as magenta sticks; water molecules shown as red spheres. (B) Close-up view of the **11a** binding pocket. Four subsites, S1', S1, S2 and S4, are labeled. The residues involved in inhibitor binding are shown as wheat sticks. **11a** and water molecules are shown as magenta sticks and red spheres, respectively. Hydrogen bonds are indicated as dashed lines. (C) Schematic diagram of SARS-CoV-2 M^{pro} -**11a** interactions shown in (B). (D) Comparison of the binding modes between **11a** and **11b** for SARS-CoV-2 M^{pro} . The major differences between **11a** and **11b** are marked with dashed circles. The compounds of **11a** and **11b** are shown as magenta and yellow sticks, respectively. (E) Close-up view of the **11b** binding pocket. Hydrogen bonds are indicated as dashed lines. (F) Schematic diagram of SARS-CoV-2 M^{pro} -**11b** interactions shown in (E).

Fig. 4. Comparison of the inhibitor binding modes in SARS-CoV and SARS-CoV-2 M^{pro}s. (A) Comparison of binding modes of 11a in SARS-CoV-2 M^{pro} with those of N1, N3 and N9 in SARS-CoV M^{pro}. SARS-CoV-2 M^{pro}-11a (wheat, PDB code: 6LZE), SARS-CoV M^{pro}-N1 (sky blue, PDB code: 1WOF), SARS-CoV M^{pro}-N3 (gray, PDB code: 2AMQ) and SARS-CoV M^{pro}-N9 (olive, PDB code: 2AMD). 11a, N1, N3 and N9 are shown in magenta, cyan, dirty violet and salt, respectively. (B) Comparison of the 11a and N3 binding pockets. Residues in M^{pro}-11a structure and M^{pro}-N3 structure are colored in wheat and gray, respectively. 11a and N3 are shown as sticks colored in magenta and dirty violet, respectively. (C) Comparison of binding modes of 11b in SARS-CoV-2 M^{pro} with those of N1, N3 and N9 in SARS-CoV M^{pro}. SARS-CoV-2 M^{pro}-11b (pale cyan, PDB code: 6MOK). 11b, N1, N3 and N9 are shown in yellow, cyan, dirty violet and salt, respectively. (D) Comparison of the 11b and N9 binding pockets. Residues in M^{pro}-11b structure and M^{pro}-N9 structure are colored in pale cyan and olive, respectively. 11b and N9 are shown as sticks colored in yellow and salt, respectively.

Fig. 5. In vitro inhibition of viral main protease inhibitors against SARS-CoV-2. (A and B) Vero E6 cells were treated with a series concentration of indicated compounds **11a** and **11b** and infected with SARS-CoV-2 at an MOI of 0.05. At 24 hours post infection, viral yield in the cell supernatant was quantified by plaque assay. The cytotoxicity of these compounds in Vero E6 cells was also determined by using CCK8 assays. The left and right Y-axis of the graphs represent mean % inhibition of virus yield and mean % cytotoxicity of the drugs, respectively. (C and D) Viral RNA copy numbers in the cell supernatants were quantified by qRT-PCR. Data are mean $\pm$ SD, $n = 3$ biological replicates.
